Thus, assessing the role of diet, physical activity and healthy behaviors on healthy aging is of utmost importance. The purpose of the current study was to examine the relationship between lifestyle factors and the odds of healthy aging. Data were obtained from the 2011-2012 and 2012-2013 Australian Longitudinal Study on Women's Health. Multinomial logistic regression was used to examine the independent contribution of factors on healthy aging, including physical activity, alcohol use, BMI, and food choice. Interactions between the predictors were tested. After controlling for age, an elevated BMI, increasing alcohol use, and physical activity were inversely associated with healthy aging. Of those who reported exercising less than three times a week, women aged 55 and over were at greater odds of healthy aging than those who were inactive. In comparison, those who reported engaging in high-intensity exercise less than three times a week were more likely to be healthy than those who were inactive, although this was only significant for those who were aged 50 and over. Increasing age was inversely related to healthy aging, whereas, among those who exercised, only the older women were more likely to be healthy. Women were more likely to be healthy than men. Age was positively related to healthy aging and inversely related to unhealthy aging. Physical activity, BMI, and alcohol use were positively related to healthy aging.
